Job burnout

Turnover intention

Perceived organizational support

## ABSTRACT

This study explores through the lens of the banking service sector the relationship between customer orientation and job burnout through emotional labor (deep acting and surface acting), and its impact on reducing turnover intention. This research also examines the moderating role of perceived organizational support (POS). Surveying 688 frontline employees working in commercial banks in Vietnam, the authors deployed a research framework based on the conservation of resources theory, job-demand resource model, and social exchange theory and used the partial least squares structural equation modeling (PLS-SEM) to test the research hypotheses. The findings indicated that the two types of emotional labor mediated the association between customer orientation and job burnout. POS also dampened the relationship between job burnout and turnover intention. Finally, the study suggested implications for bank managers to reduce job burnout and employee turnover intention.

## 1. Introduction

More than ever in recent history, organizations have been forced to focus significant commercial attention on the nature and quality of services provided to customers because of increased competition among service providers and the rapid growth being experienced in the service economy (Tang & Xiu, 2021). In the new economics of service, top-level executives of service-orientated organizations are acutely aware that frontline employees and customers should be their central foci, as service delivery can provide a cogent competitive advantage. Service organizations, particularly, are encouraged to consider how employees perform at the customer interface to further strengthen organizational market advantage (Kandampully & Solnet, 2020). The frontline employee's behavior and attitudes are therefore considered a critical factor in provisioning service success framed within corporate deliverables. Moreover, heightened service-orientated customer relationships serve as a valuable enabler in increasing business profits, particularly when these frontline employees expound their duties in a timely and desirable manner.

Recent academic studies have confirmed that employees in the

service industry, especially customer-facing employees, are subject to job burnout (Demerouti et al., 2021). Job burnout is used to explain the chronic and accumulative job stress of staff within a work environment (Demerouti et al., 2021). The consequences of job burnout are serious; employees become overwhelmed with emotional exhaustion, lack energy, become suspicious, easily react negatively, are heartless, or are no longer confident in their job (Schaufeli et al., 2009). The intensity of contact with customers, the duty of meeting all customer interface requirements, and ensuring customer happiness and satisfaction are all non-negotiable job criteria. Organizations within the service industry are very much interested in this issue because problems relating to job burnout can directly affect employees' turnover intention. Scholars have widely acknowledged the theory of the causal pathway between cognitive turnover intentions to actual turnover (Ngqeza & Dhanpat, 2022).

In business, especially the service industry, customer orientation (CO) is considered a crucial characteristic that allows employees to carry out their duties within the workplace (Zablah et al., 2012). Organizations integrate customer orientation into employees' job requirements, to evaluate them based on the value provided to customers (Wu & Shie,

2017). Customer orientation is considered a key adjustment tool to mitigate the effects of job burnout on turnover intention (Park et al., 2018). In the service sector, frontline employees who exhibit high levels of customer orientation strive to serve customers respectfully and enhance the quality of customer service. However, current research mainly focuses on frontline service employees in industries such as retail, restaurants, hotels, and airlines. As a result, there is a lack of academic inquiry into the experiences of frontline employees in the banking service sector.

Furthermore, burnout is a result of emotional interactions with customers and an employee's inability to replenish emotional resources, ultimately leading to exhaustion. Interactions, which require the employees to control their emotional expressions or modify their feelings, is a process identified as emotional labor (EL). Miranda and Godwin (2018) defined emotional labor as a process of working by emotion: employees are exposed to many different scenarios where their emotional displays are modified by the organizations' expectations. There are two processes within the EL model that align with the organizational display rules: (a) surface acting, the process of managing observable expression; (b) deep acting, modifying internal feelings. Research indicates that EL, specifically surface acting, results in cognitive dissonance, exhaustion, detachment, and a diminished sense of personal accomplishment. It is the sustained modification of emotional expression through faking, suppressing, or enhancing emotions that ultimately leads to burnout. This is due to internal tension that results from inauthentic interactions and physiological efforts to suppress true feelings. Further, the connection between customer orientation and job burnout with emotional labor has not been adequately investigated. Much of the recent focus has been on frontline employees' reactive behaviors to their jobs' emotional demands are their link to customer orientation, and as a result, research on job burnout in the banking service industry is still limited. Therefore, this research plans to explore a mediator of emotional labor that clarifies how the association between customer orientation and job burnout is founded.

Besides, Bakaç et al. (2022) emphasized the importance of employers prioritizing the safety, health, and well-being of their employees by understanding their perceived organizational support (POS). POS refers to employees' perceptions of the support they receive from their organization (Eisenberger et al., 1986). This study aims to investigate how POS influences the relationship between job burnout and turnover intention among frontline employees. Currently, the extent to which POS moderates this relationship remains unclear.

Most research on the Vietnam service sector centers around customers, focusing on their attitudes, behavior, feelings, and satisfaction. Existing studies primarily investigate customer satisfaction with the services they receive and explore ways to enhance both satisfaction and loyalty. Essentially, all resolutions stem from the customers' perspective in the transaction. However, there are few studies that examine the human resources aspect within the banking industry, and those that do tend to be incomplete. Notably, there is a lack of research that addresses the relationship between customer orientation, emotional labor, job burnout, and turnover intentions in this sector. The banking industry is particularly significant for an emerging economy like Vietnam, which is currently experiencing growth and is projected to continue its rapid development. This growth places immense pressure on bankers to ensure customer satisfaction while also retaining and expanding their client base. The challenge is further compounded by the difficulty in accessing high-quality human resources to meet the sector's evolving needs. In response, the banking sector is striving to attract top talent by creating work environments that foster passion, enthusiasm, and commitment among employees. These efforts aim not only to enhance customer service but also to reduce job burnout and retain frontline service staff.

This study is designed to explore the significant impact of customer orientation on job burnout, emphasizing the critical mediating role of emotional labor and its subsequent influence on the turnover intentions

of frontline service employees within the banking industry. This investigation is particularly vital for the banking sector as it directly tackles the pressing challenges faced by frontline service workers, thereby capturing the audience's attention and fostering a sense of urgency. Moreover, the study will delve into the moderating effect of perceived organizational support on the relationship between job burnout and turnover intentions. The authors employ Conservation of resources (COR) theory (Hobfoll, 1989) and the Job Demands-Resources (JD-R) model (Demerouti et al., 2001) to effectively illustrate how customer orientation shapes emotional labor, job burnout, and turnover intentions. Additionally, the authors leverage social exchange theory (Blau, 1964) to illuminate the moderating impact of perceived organizational support. By shedding light on these dynamics, this research equips human resources managers in the banking sector with critical insights to understand and address the necessary development and support interventions for their employees. Consequently, organizations can implement more effective strategies to mitigate job burnout and reduce turnover intentions, ultimately fostering a healthier and more productive work environment.

## 2. Literature review

### 2.1. Related theories

#### 2.1.1. Conservation of resources (COR) theory

COR theory is built on the basis that people try to minimize resource loss (Hobfoll, 1989). The person with more resources is more likely to avoid stress than the person with limited resources. A person focuses on collecting, preserving, fostering, and protecting resources to avoid losing valuable resources. In addition, the resources are value-added elements that can create change and assist in replenishing lost resources (Alarcon et al., 2011). The first principle of COR theory focuses on the dynamic force of resource losses versus resource benefits (be motivated by loss). It means that the persons who lose their resources will motivate themselves to improve the lost resources (regain lost ones) or focus on their weaknesses and lose more resources. The second principle focuses on resource investing to protect against loss of resources, restore lost resources and promote the collection of additional resources to prevent future deficits.

#### 2.1.2. The job-demand resource model (JD-R model)

The JD-R model of Demerouti et al. (2001) posits that job demands (e.g., time pressure, physical workload, and recipient contact) increase individual job stressors, while job resources (e.g., rewards, feedback, and organizational support) decrease individual job stressors. When job demands outweigh the job resources available to the employee, employee exhaustion and disengagement increase, leading to employee burnout and, in turn, a greater likelihood of quitting. The JD-R model proposes that job demands positively affect burnout. Moreover, when job resources are high, the positive impact of job demands on burnout reduces, and consequently, employees are less likely to want to quit.

#### 2.1.3. Social exchange theory (SET)

Social exchange theory of Blau (1964) is based on the norm of reciprocity. This norm suggests that individuals feel a moral obligation to reciprocate favorable treatment in their social relationships. In organizational contexts, SET is crucial for understanding the reciprocal relationship between employees and their employers. Perceived Organizational Support reflects employees' beliefs that their organization values their contributions and cares about their well-being. According to SET, when employees perceive high levels of organizational support, they are more likely to respond with positive attitudes and behaviors, such as increased commitment and lower intentions to leave the organization. This study applies SET to explore the moderating role of POS in the relationship between job burnout and turnover intention. Specifically, when POS is high, employees who experience burnout may still

feel valued by their organization, which can reduce their desire to leave. In contrast, low levels of POS may exacerbate the effect of burnout on turnover intention, as the perceived lack of reciprocity can diminish the employee's motivation to remain with the organization.

In this study, COR theory, JD-R model, and SET theory are also used as fundamental theories, explaining the relationship among factors of customer orientation, emotional labor, job burnout, perceived organizational support, and turnover intention.

## 2.2. Customer Orientation (CO)

According to [Karatepe and Douri \(2012\)](#), customer orientation is a critical personality trait that allows employees to implement their duties at work. Customer orientation is a psychological resource that creates the desired working results because customer orientation helps shape employee perceptions and attitudes toward their work. Specifically, customer-orientated employees can timely resolve customer requirements and issues, treat customers politely and nicely, and keep a consistent level of emotion in their interaction with customers. At the individual level, customer orientation was considered as a personality trait, a mixture of attitudes and behaviors ([Zhao, 2022](#)). Frontline employees with high CO tend to provide good services more naturally. They prefer working and believe that providing timely and effective services to customers is a major function of their work. Customer orientation at the enterprise level is generalized as an organizational culture, an active collective process that leads to organizational success ([Zhao, 2022](#)).

## 2.3. Job burnout

Job burnout is a chronic matter related to a condition that is progressively developed as a result of persistent stress in the workplace. Job burnout refers to the psychological stress of workers because of chronic and accumulative job stress over a long period of time. Job burnout includes three aspects: emotional exhaustion, cynicism, and reduced personal achievement ([Maslach et al., 2001](#)). In particular, emotional exhaustion refers to "the feeling of being overwhelmed and exhausting one's emotional and physical resources" ([Maslach et al., 2001](#)). Cynicism and reducing personal achievement aid in employees' loss of confidence in their ability to finish work and doubt their contribution or influence to their organization.

According to COR theory, job burnout occurs when employees find their resources depleted, it is difficult to regain them, and as a result become stressed ([Bakaç et al., 2022](#)). As a consequence, customer orientation can be the premise supplementing for the loss of self-resource due to the demands of that particular job. Specifically, frontline employees with high customer orientation can search and gather the resources needed to overcome obstacles because they have stronger motivation to serve customers ([Wu & Shie, 2017](#)). They do not want to lose their jobs; they feel that customer satisfaction is a motivation and the passing of this stage will help them to succeed. They view the loss of resources as just temporary status and believe that the cause of the loss of resources will diminish through their efforts. Meanwhile, frontline employees with low customer orientation, who are less interested in serving and responding to customer needs, must be forced to follow the exhibited principles. Their pessimistic and passive nature, consume cognitive and emotional sources and eventually could lead to exhaustion. Therefore, frontline employees in banking services with high customer orientation are more likely to perceive their duties as vital to organizational success and thus experience low job burnout. The hypothesis is as follows:

**H1.** Customer orientation has a negative effect on job burnout.

## 2.4. Emotional Labor (EL)

Emotional labor is an essential part of the service sector. Emotional

labor has been proven to have an impact on the efficiency of organizations and individuals ([Allen & Augustin, 2021](#)). Emotional labor is defined as the management of emotional expression in order to create an appropriate visual display of the face and the body based on the organization's desires. There are two different types of emotional labor action strategies: surface acting (SA) and deep acting (DA) ([Hochschild, 1983](#)). Surface acting refers to the management of external emotional expression without any change in inner feelings, which is also known as emotional impersonation, while deep acting relates to an effort to create a desired emotional display. In the positive case, the employee represents surface acting at the request of the organization to improve organization performance or to please the service recipient. For example, employees smile because they know customers like it, though they do not feel happy. In the negative case, their smile is just made to fulfill the organizational obligations. In contrast, deep acting is a process through which employees change their internal emotions to fit the organization's expectations; the emotions created on display are natural and authentic. The fact that inner feeling is changed suggests an external manifestation along with the display principles. Thus, surface acting appears at the level of expression, and deep acting happens at the level of experience.

Some previous studies (e.g., [Kucukusta & Lim, 2022](#); [Teoh et al., 2019](#)) have shown that surface acting is more likely to lead to negative health outcomes than deep acting. The contradiction between the real emotion and the display principles leads to surface acting, which is only to implement the display principles. This leads to the emotional inhibition of employees. To solve this inhibition, frontline service employees are required to use other resources to regain emotional balance. Thus, surface acting strategy requires the investing of resources in accordance with the display principles and managing emotional imbalance. According to [Hur et al. \(2020\)](#), deep acting differs from surface acting since the self-resources need to be invested in following the display principles, and there is no managed imbalance needed. In the services sector, managers place strict demands on the attitudes and emotions of employees which must be dutifully followed when serving customers. Frontline employees must choose to demonstrate through surface acting (fake positive emotion or hide negative emotion) or deep acting (modify emotion to create real positive emotion displays) to please the customers. In order to develop positive displays, employees will adjust themselves, and this adjustment leads to the exhaustion of limited resources, which is the cause of exhaustion. According to COR theory, customer orientation could play an important role as a resource supplement for lost resources and influence which strategy should be chosen ([Lee et al., 2016](#)). Frontline employees with high customer orientation can be aware of the benefit of a successful meeting with customers. Therefore, they automatically express the desired emotion through joining in deep acting strategy and are satisfied with their job. In this case, they are less likely to choose surface acting while dealing with customers. Hence, this study proposes the following hypotheses:

**H2.** Customer orientation has a negative effect on surface acting.

**H3.** Customer orientation has a positive effect on deep acting.

Moreover, services market is getting more and more competitive. Organizations build many rules related to customer service and display them to enhance service quality and customer satisfaction. Frontline employees have to manage their emotions and make an effort to express a friendly demeanor when interacting with customers. Special acting strategies are used to meet organizational requirements: surface acting (fake emotion) and deep acting (actually experience the desired emotion). However, it is important to choose emotional strategies to serve customers because customers can also distinguish between artificial or realistic smiles, and perception of authenticity can affect customers satisfaction ([Groth et al., 2009](#)). As a result, frontline employees are directly affected by their feelings and leads to undesirable job burnout. The results of previous research (e.g., [Jeung et al., 2018](#)) have proved that frontline employees who selected deep acting are better able

to show emotion more naturally than frontline service employees selecting surface acting so they were also more satisfied with their job and escaping from the trap of job burnout. [Wu and Shie \(2017\)](#) pointed out that deep acting significantly reduced job burnout for employees, while surface acting could raise stress related to work by exhausting employees' emotions in serving customers. Thus, the following hypotheses are suggested:

**H4.** Surface acting has a positive impact on job burnout.

**H5.** Deep acting has a negative impact on job burnout.

Additionally, prior studies discovered the direct associations between customer orientation and emotional labor (surface acting and deep acting) ([Lee et al., 2016](#); [Wu & Shie, 2017](#)) as well as emotional labor and job burnout ([Han et al., 2018](#); [Wu & Shie, 2017](#)). Linking the existing relationships outlined above, the authors state that emotional labor is likely to mediate the association between customer orientation and job burnout. Thus, the following hypotheses are posited:

**H6.** Surface acting mediates the association between customer orientation and job burnout.

**H7.** Deep acting mediates the association between customer orientation and job burnout.

### 2.5. Turnover intention

[Ngqeza and Dhanpat \(2022\)](#) describe turnover intention as an individual's desire to leave the organization due to the organizational lack of meeting the individual's requirements. [Tetteh et al. \(2020\)](#) defined turnover intention as the individual's wishes not to remain in an organization to which may turn into the manifestation of the actual behavior to leave. According to [Qureshi et al. \(2024\)](#), organizations are concerned with both tangible and intangible costs associated with turnover. Tangible costs refer to costs related to recruitment, screening, interviewing, testing, training, and more. Intangible costs are associated with all other factors such as loss of productivity, increased stress on other employees, increased mistakes by new employees, additional supervision, and more.

Determining the factors that cause turnover intention and implementing a plan of action to deter such efforts may reduce actual turnover. [Cohen et al. \(2015\)](#) evaluated turnover intention and predicted actual turnover. [Cohen et al. \(2015\)](#) also confirmed that job burnout as a main variable in predicting turnover intention. Managing job burnout in the workplace is very important, especially in companies and organizations providing services. Job burnout affects not only the working attitude but also the turnover intention of each employee. The emotional, psychological, and physical conditions of the staff are found to be important determinants of the quality service provision to customers. According to the JD-R model of [Demerouti et al. \(2001\)](#), frontline service employees usually have to deal with work-related stresses, leading to high levels of emotional exhaustion. Thus, they cannot meet the job expectations in the context of orienting customer service business. Monitoring of job burnout symptoms is necessary for an organization because it does not only affect employees' turnover intention but can also have a serious effect on customers' satisfaction. Some prior researchers (e.g., [Salama et al., 2022](#)) noted that job burnout can make service employees impatient, causing an emotional gap with customers leading to service failure and high turnover intention. The following is suggested as a hypothesis for the research:

**H8.** Job burnout has a positive effect on turnover intention.

### 2.6. The moderating role of perceived organizational support

Perceived organizational support (POS) refers to the extent to which an employee believes that an organization values their contributions and cares about their wellbeing ([Eisenberger et al., 1986](#)). In other words,

POS is employees' perception that an organization treats them favorably, provides them resourcing, values their contributions, and supports them. Employees require organizational support from their employer to perform above expectations, regardless of how long they have worked for the organization. According to the job-demand resource model (JD-R model) of [Demerouti et al. \(2001\)](#), POS is a significant job resource that could help in achieving job demands. When an employee has an optimistic belief about support from his/her organization in caring for his/her career needs, it requires major resourcing to cope with job burnout, and he/she could reduce turnover intention ([Srivastava & Agrawal, 2020](#)). Further, social exchange theory postulates that employment is the exchange of effort and commitment or tangible benefits, such as pay and notoriety ([Blau, 1964](#)). When one person does something favorable to another, then the favor is likely returned favorably. Taking this approach, one can surmise that although an employee may have experienced job burnout since he/she perceives that the organization cares about him/her; they tend to reciprocate by reducing their intention to quit. Thus, the following hypothesis is posited ([Fig. 1](#)):

**H9.** POS moderates the relationship between job burnout and turnover intention. This positive association will be weaker for employees who have a high feeling of POS.

## 3. Method

### 3.1. Procedure and sample

The measurement scale for conceptual structures is derived from previous studies ([Eisenberger et al., 1986](#); [Lee, 2017](#); [Lee et al., 2016](#); [Tetteh et al., 2020](#)). The original scales were developed in English. To maintain semantic and conceptual equivalence, they were first translated into Vietnamese by a bilingual researcher with expertise in the subject matter of the study. A second bilingual researcher, who was unaware of the original English version, then independently performed a back-translation into English. Any discrepancies between the original and back-translated versions were reviewed and resolved through discussions among the translators and a third expert. This process minimized translation bias and ensured that the survey items were linguistically and culturally appropriate. The study was conducted in two phases: a pilot study and a primary survey. The pilot study, which used the qualitative method was purposively initiated to adjust the scale in measuring research concepts. The focus group method was conducted with ten frontline employees working at commercial banks in Vietnam to modify the items to ensure greater suitability for Vietnamese respondents. Participants in the focus group were chosen based on specific criteria: (1) currently employed as frontline employees at commercial banks in Vietnam, (2) having at least one year of experience in customer-facing roles, and (3) possessing a basic understanding of workplace communication and HR-related policies. These criteria were established to ensure that participants had adequate exposure to organizational practices and could provide meaningful feedback on the clarity, relevance, and cultural appropriateness of the survey items. The selection of participants was carried out through purposive sampling. Researchers contacted various bank branches in Ho Chi Minh City and invited qualified employees to voluntarily participate in the discussion. It was a priority to ensure diversity in age, gender, and job roles, as this would provide a broad range of perspectives and enhance the quality of the research findings. Each question of the measurement scale was alternatively asked for respondents' understanding and suggestions until every item was completely understood. Their opinions and recommendations for revising the wording and the number of observed items in the draft were incorporated into the official questionnaire.

For the primary survey, the authors collected a list of thirty-one commercial banks in Vietnam to undertake the survey. One of our co-authors contacted authorized persons of the commercial banks who were in charge of the human resource management department and

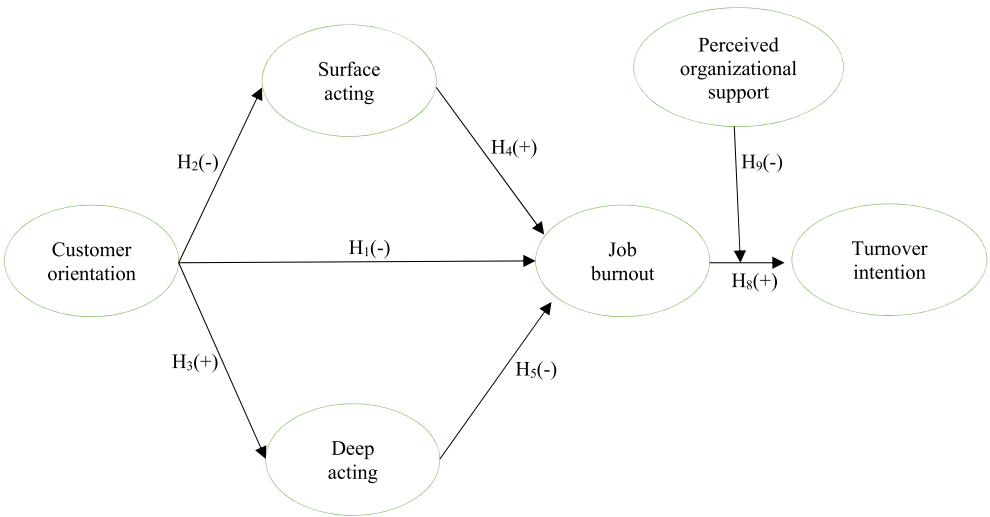

Fig. 1. The conceptual model.

clearly explained this survey's goal. Next, the authors sought permission from twelve out of thirty-one commercial banks to conduct a survey data collection. The self-administered survey method with the convenience sampling approach was employed. Sekaran and Bougie (2016) emphasized the importance of having a minimum sample size that is at least ten times the number of items in a study. Since our study includes six constructs with a total of 28 items, the minimum sample size required would be 280 (28 items  $\times$  10). However, as we collected data from 12 commercial banks in Vietnam, each with a substantial number of employees, some researchers (e.g., Jawlik, 2016) suggested that a larger sample size would help reduce bias and improve the overall representativeness of the sample to the population.

A hard copy of the questionnaire was sent directly to 1000 frontline employees of twelve commercial banks in Vietnam. The researchers collected a total of 731 completed questionnaires from September 2023 to May 2024. Among these, 43 answer sheets were not used because they were not suitable (14 answer sheets with the same answer for all questions; and the others with missing answer values). After eliminating unqualified samples, the remaining 688 samples were used to run the research. The characteristics of frontline employees were presented in Table 1.

3.2. Measurement scales

Customer orientation was measured by using the six-item scale

Table 1  
Demographics of frontline employees.

| N = 688                                            |                      | Frequency | Percent |
|----------------------------------------------------|----------------------|-----------|---------|
| Gender                                             | Female               | 470       | 68.3    |
|                                                    | Male                 | 218       | 31.7    |
| Marital status                                     | Single               | 186       | 27.0    |
|                                                    | Married              | 502       | 73.0    |
| Age group                                          | Below 25 years old   | 207       | 30.1    |
|                                                    | 26–35 years old      | 346       | 50.3    |
|                                                    | > 35 years old       | 135       | 19.6    |
| Educational level                                  | College              | 98        | 14.2    |
|                                                    | Bachelor             | 544       | 79.1    |
|                                                    | Master/Ph.D.         | 46        | 6.7     |
| Salary/month<br>(1 million VND $\approx$ \$ 42.31) | Under 10 million VND | 210       | 30.5    |
|                                                    | 10–20 million VND    | 330       | 48.0    |
|                                                    | 20–30 million VND    | 112       | 16.3    |
|                                                    | Above 30 million VND | 36        | 5.2     |
| Work experience<br>(Years)                         | Below 5 years        | 379       | 55.1    |
|                                                    | 5–10 years           | 214       | 31.1    |
|                                                    | > 10 years           | 95        | 13.8    |

developed by Lee et al. (2016). Emotional labor consists of two dimensions with 09 items (5 items for surface acting and 04 items for deep acting) from Lee et al. (2016). Job burnout scale was assessed with 04 items drawn from Lee (2017). Perceived organizational support was measured by 5 items of Eisenberger et al. (1986). Turnover intention was adapted by using the 4-item scale developed by Tetteh et al. (2020). The responses were scored on the 5-point Likert scale that had a value from 1 (strongly disagree) to 5 (strongly agree).

3.3. Data analysis

PLS-SEM was chosen to test the research hypotheses due to its flexibility and effectiveness in handling complex structural models. This study proposed a model that involves multiple latent variables and hypothesizes multidimensional relationships, including both direct and indirect effects among the constructs. PLS-SEM is particularly suitable for this kind of analysis because it aims to maximize the explained variance of dependent variables, thus supporting a prediction-oriented approach (Hair et al., 2019). This capability reassures researchers about the effectiveness of PLS-SEM in their studies. The model estimation was conducted using SmartPLS version 4.0.

4. Results

According to Hair et al. (2019), before conducting a PLS-SEM assessment for research hypothesis testing, the researchers need to measure the convergent validity, discriminant validity, and reliability of the constructs. Hair et al. (2019) also stated that convergent validity is acceptable when the outer loadings and average variance extracted (AVE) tests are equal to or larger than 0.5. The findings indicated that the outer loading of the variables varied from 0.582 to 0.923 (Fig. 2), which was above 0.5 thresholds (i.e., the minimum outer loading for turnover intention = 0.582, customer orientation = 0.747, deep acting = 0.783, surface acting = 0.832, job burnout = 0.824, and perceived organizational support = 0.779, Table 2). Furthermore, in Table 2, AVE coefficients reached from 0.633 to 0.757 (customer orientation and deep acting, respectively), which was above 0.5. Thus, all the constructs exhibited good convergent validity.

Table 2 showed the square root of AVE was considerably greater than that of all corresponding correlations. For instance, the AVE value of job burnout was 0.724, and the square root of its AVE was 0.851. This value was larger than the correlation coefficients in its column (0.497, 0.512, and 0.549) and its row (0.519 and 0.570). Therefore, all variables reached good discriminant validity.

**Table 2**  
The validity and reliability of latent variables.

|     | Reliability |       | Convergent validity |       | Discriminant validity (Fornell-Larcker criterion) |         |         |         |         |         |
|-----|-------------|-------|---------------------|-------|---------------------------------------------------|---------|---------|---------|---------|---------|
|     | CA          | CR    | MOL                 | AVE   | CO                                                | DA      | JB      | POS     | SA      | TI      |
| CO  | 0.884       | 0.886 | 0.747               | 0.633 | (0.796)                                           |         |         |         |         |         |
| DA  | 0.892       | 0.902 | 0.783               | 0.757 | 0.510                                             | (0.870) |         |         |         |         |
| JB  | 0.873       | 0.877 | 0.824               | 0.724 | −0.570                                            | −0.519  | (0.851) |         |         |         |
| POS | 0.904       | 0.910 | 0.779               | 0.724 | −0.383                                            | −0.430  | 0.497   | (0.851) |         |         |
| SA  | 0.913       | 0.916 | 0.832               | 0.741 | −0.315                                            | −0.450  | 0.512   | 0.640   | (0.861) |         |
| TI  | 0.807       | 0.858 | 0.582               | 0.640 | −0.423                                            | −0.602  | 0.537   | 0.549   | 0.562   | (0.800) |

Notes: Square roots of AVE of latent constructs were shown in the parentheses; CO = Customer orientation; DA = Deep acting; JB = Job burnout; POS = Perceived organizational support; SA = Surface acting; TI = Turnover intention; CA = Cronbach's alpha; CR = Composite reliability; AVE = Average Variance Extracted; MOL = Minimum of outer loadings

For PLS, the reliability of the concepts should be evaluated using composite reliability (CR) and Cronbach's alpha (CA) coefficients. According to Hair et al. (2019), a CR and CR of 0.7 should be employed as a cut-off point for excellent reliability. Table 2 specified that the minimum values of CR and CA were 0.858 (turnover intention), and 0.807 (turnover intention), respectively, which were greater than the 0.7 requirements. Consequently, the reliability of the latent variables was satisfied.

Hair et al. (2019) also specified that the presence of multicollinearity is a problem when the variance inflation factor (VIF) is above five thresholds. Table 3 displayed that the maximum value of VIF statistics of the concepts was 1.547. So, the possibility of a multicollinearity problem was not a concern. Additionally, the authors tested the likelihood of common method bias (CMB) that could happen in this study's cross-sectional data. To address this problem, Podsakoff et al. (2003) posited that scholars should use Harman's one-factor test. The exploratory factor analysis found that the single factor explained only 29 % of

**Table 3**  
Inner VIF Values.

|        | CO | DA    | JB    | POS | SA    | TI    | POS*JB |
|--------|----|-------|-------|-----|-------|-------|--------|
| CO     |    |       |       |     |       |       |        |

Notes: Moderating effect = POS\*JB.

negative association between customer orientation and job burnout, the finding confirmed their significant relationship ( $\beta = -0.376$ ;  $p = 0.000$ ) (Table 4). Consequently, hypothesis 1 was supported. This result was comparable with previous studies by Wu and Shie (2017).

Hypothesis 2 posited that customer orientation is negatively connected with surface acting. The results showed that this negative relationship was statistically significant ( $\beta = -0.315$ ;  $p = 0.000$ ) (Fig. 3). Therefore, hypothesis 2 was accepted. Hypothesis 3 predicted that customer orientation and deep acting were positively associated. The finding verified their significant positive relationship with  $\beta = 0.510$  and  $p = 0.000$  and supported hypothesis 3. These findings were consistent with the previous research of Lee et al. (2016), which showed that customer orientation increases deep acting and decreases surface acting.

For hypothesis 4 and hypothesis 5, the positive association between surface deep and job burnout was significant ( $\beta = 0.309$ ;  $p$ -value  $< 0.001$ ). Also, the negative relationship between deep acting and job burnout was significant ( $\beta = -0.188$ ;  $p$ -value  $< 0.001$ ) (Table 4), which was appropriate to prior studies of Wu and Shie (2017). Thus, these results supported hypothesis 4 and hypothesis 5.

For hypothesis 6 and hypothesis 7, the results posited that the

negative linking between customer orientation and job burnout was partially mediated by surface acting and deep acting because of the following reasons: firstly, the  $p$ -values for the direct paths: CO → JB; CO → SA; SA → JB; CO → DA; DA → JB were 0.000 (Table 4), which were significant. Secondly, the indirect effects: (CO → SA → JB) and (CO → DA → JB) were also significant with a  $p$ -value  $< 0.001$  (Table 5). So, the mediating roles of surface acting and deep acting existed. Subsequently, hypothesis 6 and hypothesis 7 were documented, and the total effect of customer orientation on job burnout was  $-0.570$ .

For hypothesis 8, the findings displayed that job burnout positively impacted turnover intention with  $\beta = 0.343$  and  $p$ -value = 0.000 (Table 4). It is in proportion to previous research by Salama et al. (2022), which confirmed that job burnout could lead to turnover intention. Hence, hypothesis 8 was statistically supported.

For hypothesis 9, which predicted that POS moderates the influence of JB on TI, the authors tested this hypothesis by evaluating the impact of the moderating effect (POS\*JB) on TI. The interaction had a negative sign and was significant as well ( $\beta = -0.065$ ;  $p = 0.032$ ) (Table 4). This finding implied that the positive relationship between job burnout and turnover intention was dampened by frontline employees with high

**Table 5**

The mediating effect of emotional labor.

| Hypothesis     | Relationship | Direct effect | Indirect effect | Total effect | Mediating effect  | Result   |
|----------------|--------------|---------------|-----------------|--------------|-------------------|----------|
| H <sub>6</sub> | CO→SA→JB     | −0.376***     | −0.096***       | −0.570***    | Partial Mediation | Accepted |
| H <sub>7</sub> | CO→DA→JB     |               | −0.098***       |              |                   | Accepted |

\*\*\*  $p < 0.001$ .

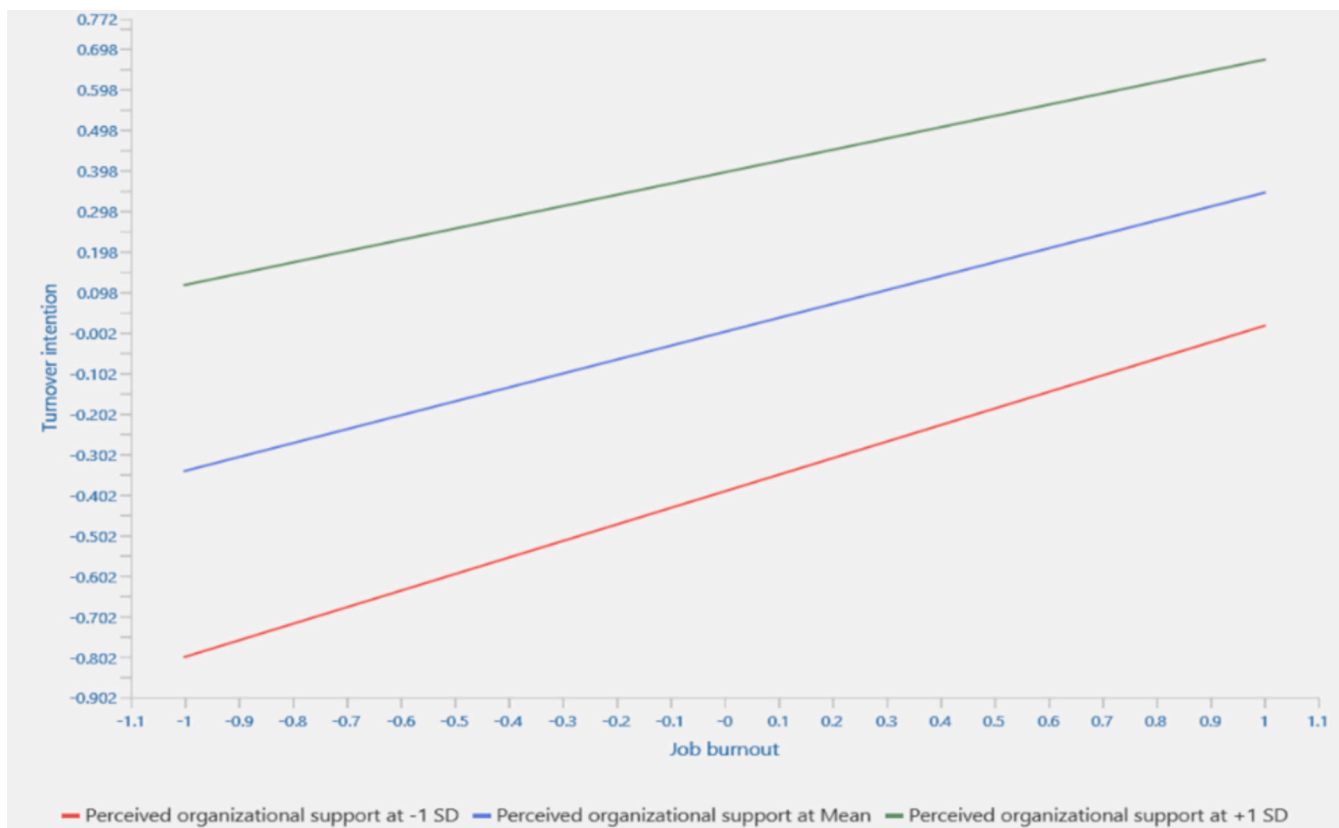

POS. To obtain a clear picture of the moderating role of POS, SmartPLS automatically created the regression lines in the analysis of the moderating effect from the standardized coefficients of the latent variables (Fig. 4). Fig. 4 illustrates how perceived organizational support (POS) influences the relationship between job burnout and turnover intention. The graph demonstrates a clear trend: as job burnout increases, the intention to leave the organization also rises. However, the degree of this increase varies based on the level of POS. For employees with low POS (represented by the red line), the relationship between burnout and turnover intention is particularly steep. This indicates that even moderate levels of burnout can lead to a significant increase in the desire to leave the organization. In contrast, employees with high POS (illustrated by the green line) show a much flatter slope, suggesting that strong organizational support can mitigate the negative effects of burnout. As a result, these employees are less likely to consider leaving, even when they are feeling exhausted. The moderate POS group (depicted by the blue line) falls between these two extremes, reflecting a varying impact based on the level of support. These observations highlight the crucial role of perceived organizational support in managing both burnout and turnover intention in the workplace. Hence, hypothesis 7 was accepted.

Lastly, Fig. 3 exhibited that  $R^2$  were 0.470 and 0.398 for the endogenous latent variable of job burnout and turnover intention, respectively. This referred that customer orientation, surface acting, and deep acting explained 47 % of the variance in the job burnout of frontline employees. Besides, job burnout explained 39.8 % of the

variance in turnover intention. Furthermore, Wetzels et al. (2009) posited that “ $R^2$  values and the effect of endogenous latent variables in behavioral sciences are assessed as 0.26 (large effect), 0.13 (moderate effect), and 0.02 (weak effect)”. The  $R^2$  values for job burnout and turnover intention were above 0.26. So, the conceptual model of this study reached the model's data fit.

## 5. Discussion

The findings of this study compellingly reinforce the direct relationships between customer orientation and emotional labor, customer orientation and job burnout, as well as emotional labor and job burnout. These results are consistent with previous research by Wu and Shie (2017) and Lee et al. (2016), but they go a step further. Unlike earlier studies that merely examined the direct relationships among these variables, this research critically investigates the mediating role of emotional labor, thereby addressing a crucial gap in the existing literature, as demonstrated by hypotheses H6 and H7. Additionally, while previous studies focused exclusively on job burnout as the consequence of customer orientation, they failed to consider the critical dimension of employees' turnover intentions stemming from job burnout. This research advances the understanding of these dynamics by confirming hypothesis H8, which incorporates turnover intention as a vital outcome of job burnout. Moreover, past studies predominantly approached the issue from the employee level, overlooking the significant influence of

**Fig. 4.** POS dampened the positive association between JB and TI.

organizational factors in alleviating job burnout and turnover intention. This study innovatively integrates an organizational-level variable—perceived organizational support—highlighting its essential role in mitigating these challenges, as articulated in hypothesis H9. The implications of these findings for organizational behavior and human resource management are profound, offering a comprehensive framework that elucidates the intricate relationships among customer orientation, emotional labor, job burnout, turnover intention, and perceived organizational support—areas inadequately addressed in prior research. This study not only fills existing gaps but also provides actionable insights for organizations seeking to improve employee well-being and retention.

## 6. Implications

### 6.1. Theoretical implications

The findings of this research expound a variety of significant theoretical implications. First, the current research expanded empirical studies by illuminating a fundamental mechanism by which customer orientation negatively impacted job burnout, and in turn, damaged turnover intention. Customer orientation proved to be a viable personal resource in reducing job burnout and turnover intention of frontline employees. Hence, this study found that customer orientation was a theoretically relevant construct for understanding the COR theory, and this study's main contribution was to provide a deeper understanding of how customer orientation led to lower job burnout through emotional labor. According to COR theory, employees with high customer orientation can express more realistic feelings and decrease the surface level's disadvantage. Customer orientation affected the surface acting, deep acting, and job burnout of the frontline employees in the banking sector in Vietnam, indicating that most of the staff had high customer orientation. This means that they are aware that customer orientation is a necessary condition of their work, that they can understand the needs of their customers and solve their problems, and that they can effectively deal with their stress to neutralize or reduce the adverse effects of job burnout.

Secondly, customer orientation played an important role in decreasing surface acting and increasing deep acting of frontline employees. Frontline employees with high CO tend to suppress negative emotions or fake positive emotions (i.e., surface acting). Also, the positive association between CO and deep acting revealed that it's helpful in any selection of emotional labor strategies represented in the authenticity of the emotional display, with or without emotional regulation. This finding concurred with the existing literature, which showed that customer-oriented employees are likely to invest effort and time in collaborating with customers to deliver accurate and reliable services.

Thirdly, this study also identified the association and routes between emotional labor and job burnout. Surface acting had a direct influence on increasing job burnout, while deep acting decreased job burnout. These findings were comparable to the results of prior scholars (Wu & Shie, 2017). Surface acting concentrates on external behavior. When frontline employees recognize that they need to suppress their emotions and express emotions demanded by employers as technical parts of their job, surface acting could increase job burnout. In other words, the results indicated that if frontline employees continue to be exposed to excessive customer and employer demands to control their feelings; they will employ surface acting to fulfill their duties. As a result, these frontline employees feel demotivated and thus more likely to experience job burnout. Moreover, this study found that deep acting reduced frontline employees' job burnout because it included the process of changing one's thoughts. Therefore, developing a strategy and a program on deep acting-oriented emotion control is necessary to decrease job burnout among frontline employees.

Fourthly, all prior scholars have only confirmed the direct relationship between customer orientation and job burnout. This investigation

posits a new variable for mediating mechanisms: “emotional labor”. By doing so, it enhances existing literature by offering the mediating role of emotional labor (surface acting and deep acting) as a potential factor when considering human resources measures in the banking industry. This research also expands on earlier studies by demonstrating the mediating role of surface acting and deep acting, which are not present in existing literature.

Finally, an organization needs to find ways to prevent the outcome of turnover intention. The moderating role of POS has been considered advantageous in reducing the disposition of frontline employees to leave their organization. The results showed that POS moderated the positive association between job burnout and turnover intention. In other words, frontline employees who positively evaluate the support provided by their organization are more likely to dampen the positive effect of job burnout on turnover intention. This result also confirmed the validity of the JD-R model and SET theory in the context of the banking industry.

### 6.2. Practical implications

Pursuing the “Customer is God” philosophy is still a top priority in the service sector, particularly in banking services. With this philosophy, customer orientation refers to the attitudes and behaviors of employees when serving customers; they must express an interest in the needs and desires of customers by the organizations' requirements. In Vietnam, this philosophy is still used as a motto of this sector. According to the study results, customer orientation had an impact on emotional labor (surface acting and deep acting) and job burnout, which, in turn, reduced turnover intention. Some implications to managing and training staff in the banking sector in Vietnam are as follows: Firstly, the results indicated that customer orientation is a significant resource that could enrich the emotional demands. Frontline employees with high CO might decrease surface acting and increase deep acting, therefore, reducing job burnout and turnover intention. This finding proposes that when recruiting and selecting employees to work at frontline positions, banks should be mindful of selecting candidates who have high customer orientation. One way for banking leaders to select customer-oriented employees is to invite potential employees to complete a customer orientation screening survey. Frontline employees with high customer orientation expect a more positive work environment in the future. This is due to the resourcefulness, service mindset, self-confidence, experience, optimism, agile learning, the desire to improve their capacity by developing new skills and mastering new situations and the enjoyment they receive when dealing with customers, their needs and issues.

Secondly, the results also showed that surface acting increases job burnout while deep acting decreases it. Therefore, managers should train frontline employees to control emotional labor appropriately. Greater focus should be placed on developing courses to train for problem-solving skills, the skill of controlling emotional labor, and stress reduction. These training programs should also include practical activities to help them better understand customers' perceptions; role-playing activities, and handling situations are essential: programs that help employees experience positive emotions, and empathy with customers: helping employees understand the use of positive emotions instead of negative emotions is a necessity. Instead of learning how to act toward customers, the employees should place themselves into customers' situations to more empathetically understand the customers' needs and requirements. Here, the use of situational simulations, is invaluable. Within a multitude of varying scenarios, employees will be exposed to customers with different attitudes, thus allowing them to build emotionally appropriate responses in a more managed and healthy way.

Thirdly, banks should aim to decrease the impacts of job burnout, and encourage employees to increase customer orientation to reduce their turnover intention. A good strategy may include a reasonable regulation of salary and monetary rewards: an impartial KPI assessment, transparent system of position, duty, and process; The rules attached to the award, such as the employee of the year, the best employee of the

month or the employee with the strongest positive customer feedback from customers in the year, should motivate employees to better contribute to the bank's service goals. In this case, employees will likely consider the bank's development as their success and thus maintain a higher customer orientation.

Finally, one of the necessary implications of this research is that it provides insight for banking managers, of the important role of perceived organizational support in lessening the positive relationship between job burnout and turnover intention among frontline employees. Leaders should promote a friendly work environment as well as form policies and practices for supporting frontline employees and their well-being.

7. Limitations and future research

This study acknowledges several limitations that should be given due consideration. Firstly, this study uses cross-sectional data, which has been collected at one point in time. As a result, it makes us cautious about conclusions regarding causal relationships among constructs. Future investigations should therefore apply a longitudinal design to provide a deeper understanding of their relationships. Secondly, the

research is framed by the variables contained in the conceptual model. Other variables could potentially affect job burnout and turnover intention, such as gender, marital status, age, income, and educational level. Further research is needed to take account of these additional dimensions. Finally, this research focuses on commercial banks in Vietnam only. Therefore, there are many possibilities and considerable scope for future research in other sectors with frontline interfaces, i.e., manufacturing industries, education, and public administration.
